

FMB641Manual CAN Requests

[Main Page](#) > [Professional Trackers](#) > [FMB641](#) > [FMB641 Configuration](#) > **FMB641Manual CAN Requests**

To use **Manual CAN request functionality** user should select **Manual CAN Requests tab** in configurator. Afterwards, user will be able to configure CAN parameters in Manual CAN Request settings tab.

Manual CAN Requests

The main benefit of using **Manual CAN requests functionality** is that the user is able to read data via CAN BUS without requiring additional CAN protocol development from the device's firmware side, if parameters needed to be requested more frequently or vice versa. To read data with this functionality, the user must have:

- **FMB641** device
- **03.01.00.Rev.00** or newer firmware (for **FMB641/FMC650/FMM650**)
- Transport or equipment with CAN interface which works via *J1939 protocol*
- Transport or equipment CAN communication protocol (with information about *frames, parameters, ID's, Baudrate*)

Manual CAN requests I/O settings

User can configure up to 70 Manual CAN Request elements by setting **CAN ID/Request ID, Request Period, Request Data Length, RTR parameters**. Additionally, in **Manual CAN I/O tab**, user needs to choose by configured Manual Request input name - **CAN type, Data mask Data Source, CAN ID**. Each CAN I/O has its own parameters and can be configured independently. Configured CAN request will be shown by **Manual CAN IO AVL ID**.

(!)

Functionality
will work
only when
Ignition is
ON

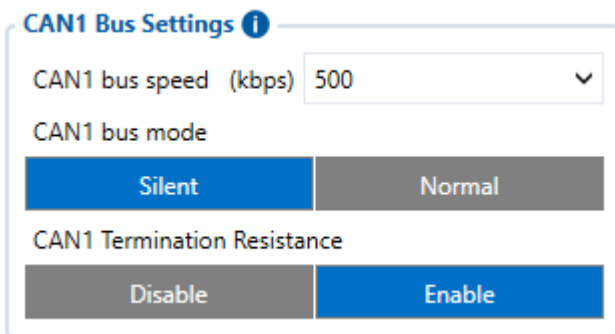

Baudrates are configurable in *CAN \ Tachograph* tab settings for connected CAN line which could be

CAN1 or CAN2.

For **Manual CAN request** functionality, CAN is selected in *Manual CAN IO tab*. In *Manual CAN IO*, the input which should receive value must be **enabled**.

- **Request ID/PGN** - depends on CAN Type parameter and defines which CAN ID will be requested by device.
- **Payload** - defines data bytes, which are send if **RTR** (Remote Transmission Request) is disabled.
- **Request Period** - defines how often the request will be send. If 0 is selected - ID will not be requested.
- **Request Data Length** - defines data length of requested ID.
- **RTR** - Remote Transmission Request, is the choice if data frame needs to be send (**if disabled**) and if data frame needs to be requested (**if enabled**).

If the data must be requested to receive CAN information from a heavy duty vehicle - **RTR must be enabled**. If data can be received without requesting it from a heavy duty vehicle - **RTR can be disabled**.

Example

In the Tachograph/CAN section the user has to select suitable baudrate. Manual CAN baudrate should be visible in the CAN protocol. If it is not known, the user can try to choose different baudrates to indicate which one works.

1. Select **CAN Type**. Normally, every CAN protocol documentation should mention which CAN type to use. If not, select **Extended**.
2. Fill in the correct **Data mask**. This field determines which IO elements of the frame the user will receive. As an example, the part of the CAN protocol was taken. Firstly, the user has to locate the data frame, which he wants to read, for this situation, data frame „**Battery status**“ was taken into account. It holds five I/O parameters of the battery. If we would like to receive all data of the frame, in the configurator the user has to leave the default value in the *Data mask field (Selected ALL)* - which is used in this example.

If the user would like to get everything except, for example, the **Battery Temperature** value, some modifications have to be done to the Data mask field. In this case, if the user does not want to get the **Battery Temperature** value, he should find where this information stands in the data frame

(byte orientation). For this example, **Battery Temperature** parameter can be found between **4th** and **5th** byte of the frame. It is explained in the table below how the 8 byte CAN frame breaks down and which part of the frame has to be changed according to this example.

Protocol example

Frame ID	Name	Period [ms]	Byte orientation	Bit	Description	Scale factor	Source addresses	Priority
0x620	Range Estimation	1000	1	7:0	Estimated range km	1 km	17	1
					Average of the two batteries SoC %			
			0	7:0	SoC second battery %	1 %		
0x300	Battery status	On request	1	7:0	Battery Current (A)	0,0625 A	18	2
			3:2	7:0	Battery Temperature (C)	0,1 C		
			5:4	7:0	Battery Voltage (V)	0,046 V		
			7:6	7:0	Battery charge enable			
0x451	Battery fast charging enable/disable		0:3	7:0	Battery charge enable	ON/OFF	19	3
			4:7	7:0	Battery charge disable			
					00001 - request SOC 1st			
					00010 - request SOC 2nd			
0x301	Battery Status message request		0:1	5:0	00100 - request Current		18	2
					01000 - request temperature			
					10000 - request voltage			
**0x452	Battery Fast charging mode switch status		0:1	2:0	01 - Charge enable		19	3
					10 - Charge disabled			
*0x453	Battery Fast charging mode switch		0:1	2:0	01 - Charge enable		19	3
					10 - Charge disable			

** - CAN ID to send CAN COMMAND

* - CAN ID to receive value in Manual CAN of CAN COMMAND

1. Enter correct **CAN ID** in *Manual CAN tab*. In this case, the **Frame ID** is needed to be entered. Here, CAN ID is 0x300, so in the configurator the user will need to enter 300 instead of last three F values (*FF0300FF*). This means that it will take the data **only** from the **ID 300**.

2. For *Manual CAN Requests* tab configuration. In **Manual CAN0 Request** will be configured Battery Status message request by the provided documentation. For proper configuration by the protocol, **Request ID** should be entered with **Source addresses**, **Frame ID** and **Priority** - 18030102, and the payload *0000000000000002* to receive all needed information.

3. Additionally, it can also have request period configured. **As an example**, to receive data each **10 seconds**, request period must be set to **10**.

4. Request data length configured as 8 bytes

5. Received I/O values are RAW and the user has to decode it. The image below is an example of how it can be decoded using additional software (we have used *Busmaster* for this):

CAN I/O

Input Name	Current Value	Units	Priority	Low Level	High Level	Event Only	Operand
Manual CAN0	0x29290000F900A504		None Low High Panic			Crash Yes No	Monitoring
Manual CAN1	0x0000000000000000		None Low High Panic			Crash Yes No	Monitoring

BatteryStatus 0x300 1 8 Std 10 a

Battery Status frame with ID 300

Send Message Delete Delete All

Data Byte View (HEX) Received value via Manual CAN for Battery Status frame

Index	00	01	02	03	04	05	06	07
000	29	29	00	00	F9	00	A5	04

Signal Details

Signal Name	Raw Value	Physical Value	Unit
Average_of_the_two_batteries_SOC	29	41	%
SOC_second_battery	29	41	%
Battery_Current	0	0	A
Battery_Temperature	F9	24.9	C
Battery_Voltage	4A5	54.694	V

5 I/O parameters listed in Battery Status frame

Decoded values for Battery Status frame

	7	6	5	4	3	2	1	0
0	0	0	1	0	1	0	0	1
1	0	0	1	0	1	0	0	1
2	0	0	0	0	0	0	0	0
3	0	0	0	0	0	0	0	0
4	1	1	1	1	1	0	0	1
5	0	0	0	0	0	0	0	0
6	1	0	1	0	0	1	0	1
7	0	0	0	0	0	1	0	0

Important note

Enabling all commands could drastically **increase** delay - sending could take up to **1.5 s** (all commands configured with 100 ms period).

We strongly advise:

1. If all commands are necessary with certain period - keep all commands with same sending period.
2. Do not leave any enabled CAN reading parameters if CAN reading is not used.
3. Keep Data Acquisition settings with higher than 15 seconds.

Send Period details

Records could drastically increase CAN command sending period as records could be generated every second by configured Features records,

NOTE!

Data Acquisition settings or IO element operands. Each particular case has different affect for CAN Command delay, that depends on configuration and in case of issue should be investigated individually.
